

# Integrating recording systems for the benefit of animal health

Improving animal health and welfare is a high priority throughout the EU. Due to the complexity involved in dealing with infectious diseases, effective long-term strategies for disease prevention, control and management will require progress in a number of areas, such as movement control, surveillance, epidemiology, diagnosis, vaccines and animal breeding.

Developments in most of these areas depend on good quality data being collected for many animals - quite often the same kind of data. Clearly, much could be gained from developing effective and integrated local, national or international recording systems that could provide data for the different uses.

In order to identify the opportunities for developing better collaborations and deriving greater benefits, we first need a good description of all the recording systems that are currently in place. This project is aimed at doing just that.

## The key to success is first assessing where the opportunities are!

---

### The focus

Developing an overview of the current health recording systems in:

- Denmark, France, the Netherlands, and the UK
- for pigs, poultry and cattle.

---

### The information we need

To be successful we need inputs from people with good knowledge of the different recording systems currently in place and planned future changes.

---

### Your help would be most welcome

If you have good knowledge of any current recording systems in these countries we would very much like to hear from you.
